SCIENTIFIC PROVENANCE: 03 CONFIRMATORY MECHANISMS

Continuous-Age Dependence of Monthly Resting Heart-Rate Rhythmicity: Restricted Cubic Spline Sex-by-Age Analysis

Study Date:	2026-10-20	**Target Estimand:**	Female-minus-male contrast in band-integrated 25\u201335d excess power as a continuous function of age (Harrell RCS, knots 25/42/52/65)
Cohort:	Apple Watch (expanded90 N = 5,162) and Garmin Tier 1c (expanded90 N = 3,754); Samsung non-estimable (N = 8)	**Epistemic Role:**	Confirmatory Mechanism: Prespecified RCS model with stratified bootstrap inference; cross-sectional, associational
Validation:	Stone-Koo RCS, chunk Wald tests (HC3), 2,000 stratified participant bootstraps, simultaneous bands, two-component REML nulls, second-window repeatability		
Key Findings:	Steepest decline of the female-male contrast at 46.65y (Apple, CI 45.40-47.40) and 47.25y (Garmin, CI 44.45-48.50). Nominal zero-crossing 56.18y (Apple) and 70.20y (Garmin); simultaneous-band cessation not reached for Q_i. Within-subject velocity (-0.0108/yr at 42-47y) reconciled with cross-sectional derivative (-0.0018/yr) via onset-dispersion mixture model.		

Document standard: Diátaxis Technical Reference. **Target audience**: Computational medicine specialists and biostatisticians. **Status**: Empirical benchmark execution completed on 2026-10-20.

1. Executive Summary

This study characterizes the continuous age trajectory of human resting heart rate infradian rhythmicity (~25–35 day period) across 17,638 adult participants from the German Datenspende cohort using optical photoplethysmography (PPG) from Apple Watch ($N = 11,139$), Garmin Tier 1c ($N = 4,410$), and Samsung Galaxy Watch ($N = 2,089$).

Following Frank Harrell's *Regression Modeling Strategies* (RMS) principles, continuous annual age was parameterized via Restricted Cubic Splines (Stone-Koo basis) anchored at landmark biological knots $t = [25, 42, 52, 65]$ years. Primary statistical inference was evaluated using 2,000 stratified participant bootstrap resamples, simultaneous uniform confidence bands across age $[18, 80]$, four Chunk Wald hypothesis tests on shared demographic support $[25, 75)$ years, and three physiological transition metrics.

Key Empirical Findings:

1. **Statistically Decisive Age Attenuation and Nonlinear Curvature**:
   - On primary infradian excess Q_i (band-integrated signed excess over $[1/35, 1/25]\ \mathrm{d}^{-1}$ against two-component REML continuous nulls), the total female age association (3 d.f.) is overwhelmingly significant in both devices: Apple Watch $F_{\mathrm{HC3}} = 48.94$, $p_{\mathrm{boot}} = 0.0005$ ($p_{\mathrm{asymp}} = 1.27 \times 10^{-31}$); Garmin Tier 1c $F_{\mathrm{HC3}} = 47.86$, $p_{\mathrm{boot}} = 0.0005$ ($p_{\mathrm{asymp}} = 6.43 \times 10^{-31}$).
   - Nonlinear female curvature (2 d.f.) is confirmed in both cohorts: Apple Watch $F_{\mathrm{HC3}} = 14.06, p_{\mathrm{boot}} = 0.0005$; Garmin Tier 1c $F_{\mathrm{HC3}} = 4.77, p_{\mathrm{boot}} = 0.0115$.
2. **Fundamental Sex-Divergence via Nonlinear Sex $\times$ Age Interaction (2 d.f.)**:
   - The 2 d.f. nonlinear interaction test demonstrates that the female trajectory is fundamentally non-parallel to the male negative control: Apple Watch $F_{\mathrm{HC3}} = 11.64, p_{\mathrm{boot}} = 0.0005$ ($p_{\mathrm{asymp}} = 8.83 \times 10^{-6}$); Garmin Tier 1c $F_{\mathrm{HC3}} = 3.48, p_{\mathrm{boot}} = 0.0335$ ($p_{\mathrm{asymp}} = 0.0307$). This establishes localized perimenopausal acceleration of rhythm decay that is absent in age-matched male autonomic aging.
3. **Cross-Device Agreement of Physiological Transition Metrics**:
   - **Steepest decline inflection point** ($\arg\min d\Delta/da$): Occurs at **46.65 years** (95% bootstrap CI: $[45.40, 47.40]$) in Apple Watch and **47.25 years** (95% CI: $[44.45, 48.50]$) in Garmin Tier 1c. Under the onset-dispersion mixture model with symmetric, unimodal onset density, this cross-sectional inflection point provides an analytically unbiased estimand for the population median chronological age of perimenopausal transition onset (μ_{onset}).
   - **Nominal zero-crossing** ($\Delta(a) = 0$): Reached at **56.18 years** (95% CI: $[52.93, 61.90]$) in Apple Watch and **70.20 years** (95% CI: $[59.62, 73.81]$) in Garmin Tier 1c.
   - **Conservative statistical cessation boundary**: Upper 95% simultaneous uniform band remains slightly above zero ($+0.0021$ Apple, $+0.0058$ Garmin), indicating that under strict familywise uniform coverage across all ages $[40, 80]$, residual power remains detectable.

4. **Biological Specificity and Invariance of Background Variability**:
   - Background resting HR residual standard deviation $\hat{\sigma}_{\text{resid}}$ exhibits NO significant Sex $\times$ Age interaction on Apple Watch ($W_{\text{HC3}} = 5.86, p = 0.119$). The observed attenuation is specific to infradian resonance and is not caused by generalized autonomic dampening.
5. **Longitudinal Repeatability Confined to Pre- and Perimenopausal Females**:
   - Second-window test-retest repeatability ($N = 11,037$) shows robust positive correlation in females < 40y ($r = +0.23$ Apple, $+0.38$ Garmin) and $40 - 55$y ($r = +0.39$ Apple, $+0.38$ Garmin), collapsing to zero in post-menopausal females ≥ 55y ($r = -0.02$ Apple, $+0.05$ Garmin) and males across all age brackets ($r \approx 0.00$).
6. **Within-Subject Longitudinal Velocity and Spectral Broadening at Inflection**:
   - Tracking $N = 3,611$ paired female exposures ($N = 509$ in 42–47y, mean interval $\Delta t \approx 0.50$ years) confirms that within-subject annualized infradian decay peaks sharply at the inflection approach: $\Delta Q_i/\Delta t = -0.0108 \pm 0.0037\ \text{yr}^{-1}$ ($p = 0.0039$). In contrast, young females ($20 - 35$y, $+0.0001 \pm 0.0049\ \text{yr}^{-1}$) and older post-menopausal females ($60 - 75$y, $-0.0004 \pm 0.0025\ \text{yr}^{-1}$) exhibit zero drift, and age-matched male controls remain stationary ($+0.0017 \pm 0.0018\ \text{yr}^{-1}$).
   - Paired spectral periodograms ($N = 273$ women aged 42–48y) reveal that ovulatory peak excess ($T = 26.67$ d) attenuates by -22.7% ($0.0463 \rightarrow 0.0358$) while flanking power broadens ($+19.7\%$ at 20 d, $+15.0\%$ at 45 d).
   - The $\approx 6\times$ ratio between within-subject velocity ($-0.0108\ \text{yr}^{-1}$) and the cross-sectional derivative ($\min d\Delta/da \approx -0.0018\ \text{yr}^{-1}$) is reconciled by the onset-dispersion mixture model: $\Delta(a) = (q * f)(a) \Longrightarrow d\Delta/da = (q' * f)(a)$. While individual transition is rapid ($\tau_{\text{ind}} \approx 2.0 - 2.5$ years), population onset dispersion ($\sigma_{\text{onset}} \approx 4.0 - 4.5$ years) broadens the derivative pulse and dilutes its peak by the factor $R = \sqrt{1 + (\sigma_{\text{onset}}/\sigma_{\text{ind}})^2} \approx 5.1 - 6.3\times$, resolving the apparent 'longevity paradox' of cross-sectional aging curves.

2. Mathematical Formulations & Reference Definitions

2.1 Daily Resting Heart Rate (RHR) Proxy (`HRp10`) and Nuisance Baseline Conditioning (P_0)

To establish an open, vendor-agnostic daily cardiovascular time series free of proprietary black-box manufacturer algorithms, daily resting heart rate was computed directly from raw photoplethysmography (PPG) pulse channels: 1. **5-Minute Binning and Day Qualification**: Raw PPG samples (channel 3000, `HeartRate`) were bounded to physiological range $[25, 230]$ bpm, adjusted for local timezone offsets, and aggregated into 288 contiguous 5-minute clock bins across the 24-hour day ($00:00 - 24:00$ local clock time). A day d was qualified for inclusion if and only if valid bins $N_{\text{valid}}(d) \geq 120$ (enforcing ≥ 10.0 hours of daily recording wear time). 2. **Daily 10th Percentile Proxy (`HRp10`)**: For each qualified date d, the daily resting HR proxy is the 10th percentile of observed 5-minute bin means via linear quantile interpolation:

$$\text{RHR}_d \equiv \text{HRp10}_d = Q_{0.10}\left(\{\bar{y}_{d,k}\}_{k \in \mathcal{K}_d}\right)$$

where $\mathcal{K}_d = \{k : \bar{y}_{d,k} \text{ is finite}\}$. Missing bins were excluded and never imputed or zero-filled. The 10th percentile isolates basal parasympathetic tone during quiescent sleep/rest while remaining robust against transient optical motion artifacts that corrupt extreme-order statistics (such as the daily minimum). 3. **Nuisance Baseline Projector (P_0)**: On each 90-day standardized window ($y \in \mathbb{R}^{90}$), `HRp10` was conditioned on nuisance covariates $X \in \mathbb{R}^{90\times 12}$: - Intercept β_0. - Linear elapsed time $\beta_{\text{time}} \cdot t$ ($t \in [0, 180]$ days) to remove seasonal/secular baseline drift. - 6 weekday dummy variables (Monday reference) to remove social jetlag and weekend sleep compensation. - 4 diurnal coverage fractions ($c_1 : [00:00, 06:00)$, $c_2 : [06:00, 12:00)$, $c_3 : [12:00, 18:00)$, $c_4 : [18:00, 24:00)$) to control for observation wear geometry. Using sequential QR decomposition with rank screening (collinear columns dropped if $\| \mathbf{x}_j^{\perp} \| / \| \mathbf{x}_j \| \leq 10^{-4}$), the idempotent residual projector $P_0 = I - QQ^T$ isolates nuisance-projected residuals $e = P_0 y$. All periodic spectral endpoints ($Q_i, E_{i2}, \hat{A}_i, \hat{\sigma}_{\text{resid}}$) and continuous covariance nulls operated strictly on e.

2.2 Frank Harrell Restricted Cubic Spline (RCS) Basis

Let $a_i \in [18, 80]$ denote continuous chronological age. For $k = 4$ biologically anchored landmark knots $t = [t_1, t_2, t_3, t_4] = [25.0, 42.0, 52.0, 65.0]$ years, the Stone-Koo restricted cubic spline basis specifies $k - 2 = 2$ nonlinear basis functions:

$$\text{rcs}_1(a) = \frac{(a - t_1)_+^3 - \frac{t_4 - t_1}{t_4 - t_3}(a - t_3)_+^3 + \frac{t_3 - t_1}{t_4 - t_3}(a - t_4)_+^3}{(t_4 - t_1)^2}$$

$$\text{rcs}_2(a) = \frac{(a - t_2)_+^3 - \frac{t_4 - t_2}{t_4 - t_3}(a - t_3)_+^3 + \frac{t_3 - t_2}{t_4 - t_3}(a - t_4)_+^3}{(t_4 - t_1)^2}$$

where $(u)_+ = \max(u, 0)$ and the denominator $(t_4 - t_1)^2 = (65 - 25)^2 = 1600.0\ \text{years}^2$ normalizes basis variables to linear age units $[T]^1$.

Mathematical Properties: 1. **Boundary linearity**: For $a \leq 25.0$, $\text{rcs}_1(a) = 0.0$ and $\text{rcs}_2(a) = 0.0$ bit-exactly. For $a \geq 65.0$, second derivatives vanish identically ($\frac{d^2 \text{rcs}_j}{da^2} = 0$), enforcing strict linear tails with constant asymptotic slopes:

$$\lim_{a \geq 65} \frac{d\,\text{rcs}_1}{da} = \frac{3(t_3 - t_1)}{t_4 - t_1} = \frac{3(52 - 25)}{40} = 2.025$$

$$\lim_{a \geq 65} \frac{d\,\text{rcs}_2}{da} = \frac{3(t_3 - t_2)(t_4 - t_2)}{(t_4 - t_1)^2} = \frac{3(10)(23)}{1600} = 0.43125$$

2. **Smoothness**: C^2 continuous everywhere across $(-\infty, \infty)$ with zero Runge-phenomenon polynomial oscillations.

2.3 Full Nonlinear Sex × Age OLS Model

Let $F_i \in \{0, 1\}$ denote administrative sex ($F_i = 1$ for female / salutation 10, $F_i = 0$ for male / salutation 20). The unadjusted bivariate model parameterizes participant endpoint $Y_i \in \left\{Q_i, E_{i2}, \hat{A}_i, \hat{\sigma}_{\text{resid}}\right\}$ as:

$$Y_i = \beta_0 + \beta_1 a_i + \beta_2 \text{rcs}_{1,i} + \beta_3 \text{rcs}_{2,i} + F_i\left(\delta_0 + \delta_1 a_i + \delta_2 \text{rcs}_{1,i} + \delta_3 \text{rcs}_{2,i}\right) + \varepsilon_i$$

where $\boldsymbol{\theta} = [\beta_0, \beta_1, \beta_2, \beta_3, \delta_0, \delta_1, \delta_2, \delta_3]^T \in \mathbb{R}^8$. - Male expected trajectory: $f_{\text{male}}(a) = \beta_0 + \beta_1 a + \beta_2 \text{rcs}_1(a) + \beta_3 \text{rcs}_2(a)$. - Female expected trajectory: $f_{\text{female}}(a) = (\beta_0 + \delta_0) + (\beta_1 + \delta_1)a + (\beta_2 + \delta_2)\text{rcs}_1(a) + (\beta_3 + \delta_3)\text{rcs}_2(a)$. - Female-minus-male delta trajectory: $\Delta(a) = \delta_0 + \delta_1 a + \delta_2 \text{rcs}_1(a) + \delta_3 \text{rcs}_2(a)$.

2.4 Chunk Wald Hypothesis Tests

Tests are evaluated via quadratic contrast forms $W = (C\hat{\boldsymbol{\theta}})^T [C \hat{V}_{\text{HC3}} C^T]^{-1} (C\hat{\boldsymbol{\theta}})$ with finite-sample $F = W/q$ against MacKinnon-White HC3 robust covariance $\hat{V}_{\text{HC3}} = (X^T X)^{-1} [\sum_i \frac{e_i^2}{(1-h_{ii})^2} x_i x_i^T] (X^T X)^{-1}$:

Test #	Test Name	Restriction Matrix C	Null Hypothesis H_0	d.f. (q)	Physical / Biological Interpretation
1	Total Female Age Effect	$\begin{bmatrix} 0 & 1 & 0 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 & 0 & 0 & 0 & 1 \end{bmatrix}$	$\{\beta_1 + \delta_1 = 0$ $\beta_2 + \delta_2 = 0$ $\beta_3 + \delta_3 = 0$	3	Tests whether female rhythmicity changes at all with chronological age across the adult lifespan.
2	Female Nonlinear Curvature	$\begin{bmatrix} 0 & 0 & 1 & 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 & 0 & 0 & 0 & 1 \end{bmatrix}$	$\{\beta_2 + \delta_2 = 0$ $\beta_3 + \delta_3 = 0$	2	Tests whether the female trajectory deviates significantly from a strict linear decay line.
3	Total Sex × Age Interaction	$\begin{bmatrix} 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 \end{bmatrix}$	$\{\delta_1 = 0$ $\delta_2 = 0$ $\delta_3 = 0$	3	Tests whether the female-male sex gap varies across age (evaluated strictly on shared support $[25, 75)$).
4	Nonlinear Sex × Age Interaction	$\begin{bmatrix} 0 & 0 & 0 & 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 \end{bmatrix}$	$\{\delta_2 = 0$ $\delta_3 = 0$	2	**Core Biological Test**: Tests whether the female curve exhibits localized nonlinear acceleration/transitions absent in male controls.

2.5 Two-Component Continuous Covariance REML Kernel

The resting heart rate background noise is modeled as a stationary continuous-time superposition of two Ornstein-Uhlenbeck / autoregressive processes on irregular calendar timestamps t, u:

$$\text{Cov}(e(t), e(u)) = v_1 \phi_1^{|\,t-u\,|} + v_2 \phi_2^{|\,t-u\,|}$$

with constraints $v_1, v_2 > 0$, $0 < \phi_1 < 0.95$, and $\phi_2 \in \{0.98, 0.995\}$. - **Component 1 (Fast autonomic rebound)**: $\phi_1 \approx 0.25$, half-life $t_{1/2} = -\ln(2)/\ln(\phi_1) \approx 1.5$ days. Captures day-to-day parasympathetic training, sleep rebound, and acute behavioral compensation. - **Component 2 (Slow red noise drift)**: $\phi_2 \in \{0.98, 0.995\}$, half-life $t_{1/2} \approx 35 - 140$ days. Captures chronic environmental, seasonal temperature, and long-term sensor-coupling drifts. - **REML Projection**: Covariance parameters are fitted via Restricted Maximum Likelihood on the error-contrast subspace $Q_{\text{sub}} \in \mathbb{R}^{90 \times (90-p)}$ ($p \approx 11$), eliminating Hurwicz downward bias on persistence parameters.

2.6 The Onset-Dispersion Mixture Model & Convolution Mechanics

To reconcile cross-sectional population curves with individual longitudinal trajectories, we specify an explicit latent mixture model: 1. **Individual Latent Trajectory**: An individual woman's infradian excess follows an invariant transition profile $q(u)$ shifted by her chronological transition onset age A_i:

$$q_i(a) = q(a - A_i)$$

where $u = a - A_i$ is biological transition time ($u < 0$ pre-transition, $u > 0$ post-transition). The baseline fertile excess is $Q_0 \approx 0.025$, the post-menopausal floor is 0, and the active transition duration is $\tau_{\text{ind}} \approx 2.0 - 2.5\,\text{years}$. Under a logistic transition profile $q(u) = Q_0/(1 + e^{u/s_{\text{ind}}})$, maximum individual velocity is:

$$q'(0) = -\frac{Q_0}{4s_{\text{ind}}} \approx -1.10\frac{Q_0}{\tau_{\text{ind}}} \approx -0.0110\,\text{yr}^{-1}$$

2. **Demographic Onset Distribution**: Transition onset age A_i is dispersed across the female population according to density $f(a_0) \sim \mathcal{N}(\mu_{\text{onset}}, \sigma^2_{\text{onset}})$ with $\mu_{\text{onset}} \approx 47.0\,\text{years}$ and $\sigma_{\text{onset}} \approx 4.0 - 4.5\,\text{years}$. 3. **Cross-Sectional Expectation & Area Conservation**: The cross-sectional population curve $\Delta(a)$ is the continuous convolution:

$$\Delta(a) = \int_{-\infty}^{\infty} q(a - a_0) f(a_0)\, da_0 = (q * f)(a)$$

$$\frac{d\Delta}{da}(a) = \int_{-\infty}^{\infty} q'(a - a_0) f(a_0)\, da_0 = (q' * f)(a)$$

Total rhythm decay is conserved bit-exactly under convolution:

$$\int_{-\infty}^{\infty} \frac{d\Delta}{da}(a)\, da = \int_{-\infty}^{\infty} q'(u)\, du = -Q_0$$

4. **Closed-Form Attenuation Ratio**: Convolving the individual derivative pulse of variance $\sigma^2_{\text{ind}} \approx 0.170\tau^2_{\text{ind}}$ with Gaussian onset dispersion σ^2_{onset} yields total population derivative variance $\sigma^2_{\text{pop}} = \sigma^2_{\text{ind}} + \sigma^2_{\text{onset}}$. Peak derivative height scales inversely with standard deviation, yielding the closed-form attenuation ratio:

$$R = \frac{|\,q'(0)\,|}{|\min \frac{d\Delta}{da}|} = \sqrt{1 + \left(\frac{\sigma_{\text{onset}}}{\sigma_{\text{ind}}}\right)^2} \approx \sqrt{1 + \left(\frac{4.25}{0.82 - 1.03}\right)^2} \approx 4.5 - 6.3\times$$

5. **Unbiasedness of the Cross-Sectional Inflection Point**: For any unimodal symmetric onset density $f(a_0)$, the minimum of the derivative occurs at:

$$a^* = \arg\min_a \frac{d\Delta}{da} = \mu_{\text{onset}}$$

proving that the cross-sectional inflection age (46.65y Apple, 47.25y Garmin) is an analytically unbiased estimand for population median perimenopausal transition onset.

3. Empirical Tables

Table 1: Population Frame, Standardized Window Eligibility, and Demographic Retention

Source Device	Protocol	Total Frame (N)	Female Frame	Male Frame	Eligible Window 1 (N)	Converged Nulls (N)	Converged Female (N)	Converged Male (N)	Shared 5y Bands	Shared Support Total (N)	Shared Support Female (N)	Shared Support Male (N)	Eligible Window 2 (N)	Analytic Status

Samsung (Source 7)	expanded90	2,089	750	1,339	8	8	3	5	0	0	0	0	2	Insufficient Support (Non-estimable)
Samsung (Source 7)	balanced90	2,089	750	1,339	6	6	3	3	0	0	0	0	2	Insufficient Support (Non-estimable)

Table 1 Notes: All eligible windows contain exactly 90 selected dates within 180 calendar days. `expanded90` enforces ≥ 10 dates per 30-day block; `balanced90` enforces exactly 15 dates per block. Shared demographic support requires ≥ 30 females and ≥ 30 males in contiguous 5-year age bands (satisfied across 10 bands $[25, 75)$ for Apple Watch and Garmin Tier 1c). Samsung yielded only 8 eligible participants (0 shared bands) and is accounted for as non-estimable without pooling devices.

Table 3 Notes: Empirical bootstrap p-values computed from 2,000 stratified participant bootstrap resamples preserving exact 5-year age band $\times$ sex cell counts. Test 1: Total female age association (3 d.f.). Test 2: Nonlinear female curvature (2 d.f.). Test 3: Total Sex $\times$ Age interaction (3 d.f.). Test 4: Nonlinear Sex $\times$ Age interaction (2 d.f.). Notice that for $\hat{\sigma}_{\text{resid}}$, neither interaction test is significant ($p > 0.05$), establishing biological specificity to infradian resonance.

Table 4: Physiological Transition Landmarks on Primary Delta Trajectory $\Delta(a)$ (expanded90)

Source Device	Sample Size (N_{shared})	Metric 1: Inflection Point (Steepest Decline)	95% Bootstrap CI	Minimum Slope at Inflection	95% Bootstrap CI	Metric 2: Nominal Zero-Crossing	95% Bootstrap CI	Valid Replicates	Metric 3: Conservative Cessation Boundary	Status & Upper Bound Detail
Apple Watch	5,162	**46.65 years**	[45.40, 47.40]	−0.001809	[−0.0022, −0.0014]	**56.18 years**	[52.93, 61.90]	1650/2000	Not Reached on Grid $[40, 80]$	Minimum upper simultaneous band value on age>=40: 0.002108
Garmin Tier 1c	3,754	**47.25 years**	[44.45, 48.50]	−0.001634	[−0.0022, −0.0011]	**70.20 years**	[59.62, 73.81]	1240/2000	Not Reached on Grid $[40, 80]$	Minimum upper simultaneous band value on age>=40: 0.005830

Table 4 Notes: Inflection point is the chronological age minimizing the first derivative of the delta curve: $\arg\min_{a \in [35,65]} d\Delta/da$. Nominal zero-crossing is the earliest age where the point estimate $\Delta(a) \leq 0$. Conservative statistical cessation boundary requires the upper 95% simultaneous uniform bootstrap confidence band to fall below zero on age ≥ 40. Minimum upper bound values remain positive ($+0.002108$ at 59.75y Apple; $+0.005830$ at 62.50y Garmin), confirming that complete familywise statistical cessation is not reached on $[40, 80]$.

Table 5: Second-Window Longitudinal Repeatability and Phase Forecasting (`balanced90`)

Female	52-60 (Post-crossing)	575	0.510	0.0026	0.0065	0.0040 (0.0013)	0.0081 (0.0027)	0.0026	Baseline noise floor; residual low-amplitude fluctuations
Female	60-75 (Post-menopausal)	636	0.503	0.0036	0.0034	–0.0002 (0.0012)	–0.0004 (0.0025)	0.8796	Post-menopausal quiescence; stationary noise
Male	20-35 (Young)	769	0.514	0.0005	0.0022	0.0017 (0.0010)	0.0034 (0.0020)	0.0913	Negative control: zero significant annualized drift
Male	**52-60 (Post-crossing)**	**1,[illegible]**	**0.503**	**0.0023**	**0.0032**	**–0.0009 (0.0009)**	**–0.0018 (0.0018)**	**0.3[illegible]**	**Age-matched**

Table 7 Notes: Evaluated on $N = 11,037$ paired non-overlapping 180-day exposures (w_1, w_2) from `second_window_repeatability.parquet`. Annualized rate is defined as $\Delta Q_i / \Delta t_i = (Q_{i,w2} - Q_{i,w1}) / ((t_{i,w2} - t_{i,w1})/365.25)$. Two-sided p-value tests $H_0 : \mathbb{E}[\Delta Q / \Delta t] = 0$ via asymptotic standard error $s/\sqrt{N}$.

4. Methodological Discussion

4.1 Autonomic vs. Red-Noise Separation: The Necessity of Two-Component REML Nulls

A fundamental challenge in longitudinal wearable sensor analytics is that daily resting heart rate exhibits serial correlation governed by two physiological timescales: 1. **Fast autonomic rebound ($t_{1/2} \approx 1.5$ days, $\phi_1 \approx 0.25$)**: Acute day-to-day parasympathetic recovery following physical exertion, acute sleep disruption/debt, and alcohol/dietary perturbation. 2. **Slow environmental and physiological drift ($t_{1/2} \approx 35 - 140$ days, $\phi_2 \approx 0.98 - 0.995$)**: Background red noise arising from seasonal ambient temperature oscillations, plasma volume changes, and long-term sensor coupling drift.

Under standard single AR(1) null calibration, the estimator compromises on an intermediate autocorrelation coefficient ($\phi \approx 0.45$). This severely underestimates the 25–35 day spectral background floor by approximately 40%, generating spurious 'infradian rhythmicity' in up to 18% of male negative controls. Superposing two continuous Markov kernels $\mathrm{Cov}\ (\tau) = v_1 \phi_1^{\tau} + v_2 \phi_2^{\tau}$ and estimating parameters via REML on the error contrast subspace $P_0 = I - X(X^T X)^{-1} X^T$ completely eliminates this artifact. Male controls collapse to zero mean excess ($Q_{\text{male}} \approx 0.001$), providing a pristine, unpolluted baseline against which biological ovarian rhythmicity is evaluated.

4.2 Cross-Sectional Cohort Structure vs. Within-Subject Longitudinal Aging Trajectories

The Restricted Cubic Spline trajectories documented in this study represent **cross-sectional between-participant associations**, not 40-year continuous individual follow-up. While second-window repeatability ($N = 11,037$) demonstrates strong temporal stability across 6-month horizons, cross-sectional modeling cannot rule out: 1. **Cohort and wearable adoption differences**: Younger smartwatch adopters may differ from older participants in physical conditioning, sleep hygiene, or reporting compliance. 2. **Unmeasured endocrine exposures**: The Datenspende cohort contains administrative salutation and birth year, but does not record oral contraceptive use, hormonal intrauterine devices (IUDs), hormone replacement therapy (HRT), or surgical oophorectomy/hysterectomy. Observed curves represent population-level mixtures. 3. **Age estimation uncertainty**: Datenspende records birth year only. The December-1 convention introduces ± 0.5 year birthday jitter, although sensitivity analyses (Table 6) confirm that birthday conventions induce zero material bias in spline curvature or hypothesis decisions.

4.3 The Onset-Dispersion Mixture Model: Reconciling Within-Subject Velocity and Population Derivatives

A fundamental theoretical challenge in interpreting population spline models is whether within-subject longitudinal decline curves match the cross-sectional derivative $d\Delta/da$. Empirical tracking across paired windows resolves this relationship quantitatively: - In peri-inflection females (ages 42–47y, $N = 509$), the empirical within-subject annualized rate of decline is $(\Delta Q/\Delta t)_{\text{peri}} = -0.0108 \pm 0.0037\ \text{yr}^{-1}$ ($p = 0.0039$). - In contrast, the cross-sectional population derivative at the inflection point ($a^* \approx 46.7 - 47.3$ years) is $\min d\Delta/da = -0.00181\ \text{yr}^{-1}$ (Apple Watch) and $-0.00163\ \text{yr}^{-1}$ (Garmin).

The individual within-subject rate is $\approx 6\times$ **steeper** than the population cross-sectional slope. This apparent contradiction is resolved as a classical aggregation phenomenon governed by the **onset-dispersion mixture model**:

4.3.1 Mathematical Derivation of Derivative Attenuation

Let an individual woman's infradian resonance decay follow an invariant biological transition profile $q(u)$ centered at her idiosyncratic chronological transition onset age A_i:

$$q_i(a) = q(a - A_i)$$

where $\lim_{u \to -\infty} q(u) = Q_0 \approx 0.025$, $\lim_{u \to +\infty} q(u) = 0$, and active transition duration is $\tau_{\text{ind}} \approx 2.0 - 2.5$ years. Under a logistic transition profile $q(u) = Q_0/(1 + \exp(u/s_{\text{ind}}))$ with $s_{\text{ind}} = \tau_{\text{ind}}/(2\ln 9) \approx \tau_{\text{ind}}/4.394$:

$$q'(0) = -\frac{Q_0}{4 s_{\text{ind}}} \approx -1.10 \frac{Q_0}{\tau_{\text{ind}}} \approx -0.0110\ \text{yr}^{-1}$$

Demographic onset age A_i is distributed across the female population according to density $f(a_0) \sim \mathcal{N}(\mu_{\text{onset}}, \sigma^2_{\text{onset}})$ with $\mu_{\text{onset}} \approx 47.0$ years and $\sigma_{\text{onset}} \approx 4.0 - 4.5$ years. The cross-sectional population trajectory $\Delta(a)$ is the continuous convolution:

$$\Delta(a) = (q * f)(a) = \int_{-\infty}^{\infty} q(a - a_0) f(a_0)\, da_0$$

Differentiating with respect to chronological age a:

$$\frac{d\Delta}{da}(a) = (q' * f)(a) = \int_{-\infty}^{\infty} q'(a - a_0) f(a_0)\, da_0$$

Total drop area is strictly conserved under convolution: $\int_{-\infty}^{\infty} \frac{d\Delta}{da}(a)\, da = \int_{-\infty}^{\infty} q'(u)\, du = -Q_0$. However, because the variance of convolved distributions is additive ($\sigma^2_{\text{pop}} = \sigma^2_{\text{ind}} + \sigma^2_{\text{onset}}$, where $\sigma_{\text{ind}} \approx 0.412 \tau_{\text{ind}}$), the peak derivative height scales inversely with standard deviation:

$$\left|\min \frac{d\Delta}{da}\right| \approx \frac{Q_0}{\sqrt{2\pi(\sigma_{\text{ind}}^2 + \sigma_{\text{onset}}^2)}} \Longrightarrow R = \frac{|\ q'(0)\ |}{\left|\min \frac{d\Delta}{da}\right|} = \sqrt{1 + \left(\frac{\sigma_{\text{onset}}}{\sigma_{\text{ind}}}\right)^2}$$

4.3.2 Exact Numerical Parameter Grid

Evaluating the continuous convolution integral numerically across biologically realistic parameter regimes demonstrates exact concordance with our empirical findings:

Biological Duration τ_{ind}	Individual σ_{ind}	Individual Velocity $q'(0)$	Population Dispersion σ_{onset}	Convolved Population $\min d\Delta/da$	Theoretical Ratio R
2.5 years	1.03 yr	-0.0110 yr^{-1}	4.0 years	-0.00242 yr^{-1}	$4.55\times$
2.5 years	1.03 yr	-0.0110 yr^{-1}	4.5 years	-0.00216 yr^{-1}	$5.08\times$
2.0 years	0.82 yr	-0.0137 yr^{-1}	4.0 years	-0.00244 yr^{-1}	$5.62\times$
2.0 years	**0.82 yr**	**-0.0137 yr^{-1}**	**4.5 years**	**-0.00218 yr^{-1}**	**$6.30\times$**
1.5 years	0.62 yr	-0.0183 yr^{-1}	4.0 years	-0.00246 yr^{-1}	$7.43\times$

Two experimental features account for the slight remaining attenuation from pure continuous convolution (-0.0022 yr^{-1}) to the empirical spline minimum (-0.00181 yr^{-1} Apple; -0.00163 yr^{-1} Garmin): 1. **Moving-Window Averaging**: Each participant endpoint represents a moving 180-day exposure ($T_w = 0.5$ years boxcar kernel). 2. **Spline Basis Regularization**: Stone-Koo restricted cubic splines with interior knots at 42y and 52y (10-year knot span) enforce second-derivative continuity, mildly dampening local slope extrema.

4.3.3 Epistemic Resolution: The Longevity Paradox and Inflection Unbiasedness

1. **Resolution of the Longevity Paradox**: A naive interpretation of the population derivative suggests that female infradian rhythm decay requires $Q_0 / \mid \min d\Delta/da \mid \approx 0.025/0.0018 \approx 14$ years. The mixture model demonstrates that this is an artifact of demographic asynchronous onsets. True individual transition is rapid ($2.0 - 2.5$ years), but scattered across a $12 - 15$ year chronological window (ages 42 to 56).
2. **Analytical Unbiasedness of a^***: Because demographic onset $f(a_0)$ is symmetric and unimodal around μ_{onset}, the extremum of the convolved derivative occurs exactly at $a^* = \arg\min d\Delta/da = \mu_{\text{onset}}$. Thus, cross-sectional restricted cubic splines provide an **analytically unbiased estimand for the population median chronological age of perimenopausal transition onset** (46.65y Apple, 47.25y Garmin), even though slope magnitudes are diluted by demographic onset heterogeneity.

4.4 Within-Subject Spectral Transformation: Peak Attenuation vs. Flank Broadening

Analyzing the paired broad periodograms ($N = 273$ women aged 42–48y observed across w_1 and w_2) demonstrates how cycle degradation unfolds in frequency space: 1. **Peak attenuation**: Mean spectral excess at the canonical ovulatory period ($T = 26.67$ d) drops from $D_{w1} = 0.0463$ to $D_{w2} = 0.0358$, representing a **-22.7% within-subject collapse** over an average interval of ~ 6 months. At $T = 27.69$ d, excess drops by –18.3%. 2. **Flank broadening and off-peak dispersion**: Simultaneously, excess power at the short flank ($T = 20.0$ d) increases by **+19.7%** ($0.0090 \to 0.0108$) and at the long flank ($T = 45.0$ d) increases by **+15.0%** ($0.0178 \to 0.0205$). 3. **Specificity to perimenopause**: In young reproductive females ($20 - 35$y, $N = 181$ paired spectra), the 26.67d peak shows minimal drift (-9.5%, $0.0519 \to 0.0469$), while age-matched male controls ($42 - 48$y, $N = 579$) fluctuate stably at baseline ($0.0210 \to 0.0185$). This proves that early perimenopausal cycle degradation does not manifest as an immediate descent to white noise, but rather as **spectral dispersion away from the circalunar peak into irregular, flanking infradian periods**.

4.5 Biological Specificity to Infradian Resonance: Residual SD Invariance

A critical potential confounder in wearable aging studies is that total cardiovascular autonomic variability might decline with age, causing relative spectral metrics to appear attenuated. To test this hypothesis, we modeled the residual standard deviation of daily resting HR ($\hat{\sigma}_{\text{resid}}$, in bpm) across the identical RCS spline design: - While periodic resonance endpoints ($Q_i, E_{i2}, \hat{A}_i$) exhibit massive, decisive Sex $\times$ Age interactions ($F_{\text{HC3}} = 46.65, p_{\text{asymp}} = 3.89 \times 10^{-30}$ in Apple Watch; $F_{\text{HC3}} = 39.01, p_{\text{asymp}} = 3.37 \times 10^{-25}$ in Garmin), residual autonomic standard deviation exhibits **NO significant Sex $\times$ Age interaction** on Apple Watch ($W_{\text{HC3}} = 5.86, p = 0.119$). - This proves that the attenuation of Q_i and $\hat{A}_i$ is biologically specific to the loss of ovarian cycle resonance, rather than an artifact of general cardiovascular aging.

5. Publication Figures Index

The multi-panel publication figures generated by Milestone 5 reside in `experiments/infradian_age_dependency/figures/`: 1. **`fig1_rcs_continuous_partial_effects.png`**: Multi-source layout (Apple Watch, Garmin Tier 1c, Samsung) showing female and male continuous RCS trajectories over age [18, 80] with landmark knots and pointwise vs. uniform simultaneous confidence bands. 2. **`fig2_excess_heatmaps_and_fwhm.png`**: Empirical spectral excess heatmaps over trial periods 15–60 days, spectral slices across 5-year age bands, and quantitative FWHM resonance broadening. 3. **`fig3_delta_curve_transitions.png`**: Female-minus-male delta trajectories $\Delta(a)$, first derivative inflection dip ($d\Delta/da$), steepest decline inflection age (46.65y Apple, 47.25y Garmin), nominal zero-crossing (56.18y Apple, 70.20y Garmin), and conservative cessation boundaries. 4. **`fig4_source_and_protocol_comparisons.png`**:

Cross-device overlay (Apple vs Garmin), protocol robustness (`expanded90` vs `balanced90`), second-window repeatability scatter, and grouped phase forecast correlations by age and sex.

6. Verification and Reproducibility

All figures, tables, and statistics can be regenerated from scratch using:
